Thermal Insulation from Construction Coating Mixed with Porous Calcium-containing Solid Waste

Hsi-Chi Yang and Tsung-Pin Tsai

Abstract—To resolve the health risk from the exposure of calcium hydroxide, the target of the present work is to stabilize the solid waste and reuse it as green material for construction buildings. An efficient chemical-wet method is adopted to synthesize CaSO₄ and CaSO₄·2H₂O powders from Ca(OH)₂ waste in the presence of diluted sulfuric acid at ambient temperature. The improved thermal insulation from the construction coating mixed with porous CaSO₄ powders has been investigated. The as-prepared CaSO₄ powders are stable in atmospheric pressure and easily stored as solid waste without toxicity. The construction coating mixed with porous CaSO₄ powders offers excellent thermal insulation capability, as compared with pristine one. The enhanced performance can be attributed to the fact that the CaSO₄ powders possess a vast porous framework, allowing a large amount of air trapped in the construction coating against the thermal transfer. Since the CaSO₄ powders is efficiently prepared from toxic solid waste, the chemical-wet method exhibits a potential route to produce green construction materials for various applications due to its simplicity, high recycling ratio, non-toxicity, low cost, and environmental friendliness.

Index Terms—Thermal insulation, calcium sulfate powders, solid waste, construction coating.

I. INTRODUCTION

Calcium hydroxide, conventionally called slaked lime, is an inorganic compound with the chemical formula Ca(OH)₂. Calcium hydroxide is also called hydrated lime, caustic lime, slack lime, and pickling lime. It is a colorless crystal or white powder and is obtained when calcium oxide (called lime or quicklime) is well mixed. Calcium hydroxide is used in many applications, including food preparation and flue-gas desulfurization. Limewater is the common name for a saturated solution of calcium hydroxide. Since Ca(OH)₂ possesses a high solubility in water (i.e., limewater), it should be seriously limited because of skin irritation, chemical burning, blindness or lung damage to human kind.

To resolve the health risk from the exposure of calcium hydroxide, the target of the present work is to stabilize the solid waste and reuse it as green material for construction buildings. This work aims at the development of recycling process for reuse of calcium hydroxide. It is well known that CaSO₄ material is one of the most promising construction materials for inner decoration due to its non-toxicity, low cost, and good environmental friendliness. Several approaches have been explored to synthesize calcium sulfate materials, using hydrothermal reaction [1], reactive crystallization [2]-[4], chemical extraction using organic media [5], and calcination-acidification [6]. Our strategy is to chemically transfer Ca(OH)₂ to CaSO₄ in the presence of diluted sulfuric acid. The as-prepared CaSO₄ powders can be mixed water-soluble paint and then coated over calcium silicate plates, offering better thermal and fire resistances as compared with the original one. Since the CaSO₄ powders could be prepared from industrial solid waste, the chemical method opens a straightforward pathway to produce green construction materials, showing superior thermal resistance.

II. EXPERIMENTAL SECTION

The solid waste was collected from a food-processing factory (Taoyuan, Taiwan). The solid waste, consisted of Ca(OH)₂ and CaSO₄ (i.e., Ca(OH)₂: CaSO₄ = 8:2 in w/w), was grounded into several micrometers by using ball mill. Afterward, the solid waste was slowly added into 1 M H₂SO₄ solution. The chemical process was carried out at ambient temperature for 1 h, allowing the formation of CaSO₄ or CaSO₄·2H₂O with high chemical conversion. Finally, white powders were precipitated in the bottom of beaker and were dried at 105°C in an oven overnight.

Field-emission scanning electron microscopy (FE-SEM; JEOL JSM-5600) was adopted to observe the microstructural morphology of as-prepared CaSO₄ powders. To examine the thermal resistance, water-soluble painting mixed with CaSO₄ powders were prepared to coat over calcium silicate plates. The calcium silicate plate was carefully cut into an area of 5 × 5 cm², and its thickness was 0.5 cm. Three painting samples were prepared with 0, 5 and 10 wt% of CaSO₄ powders in water-soluble paints, which were designated to CC-1, CC-2, and CC-3, respectively. For uniformity, the paintings were first blended with a three-dimensional mixer using zirconia balls for 10 min. The as-prepared paintings were pasted on the substrates with a securing clip. The surface temperature of the painting was kept at 100°C. One thermal imaging apparatus was used to observe temperature distribution on each sample, meanwhile three thermocouples (K type) were used to detect surface temperatures of the painting. The surface...
temperatures were stabilized after the test period of 20 min.

III. RESULTS AND DISCUSSION

Fig. 1(a) and 1(b) show top-view FE-SEM image of as-prepared CaSO$_4$ powders with low and high magnification, respectively. The photos reveal that the as-prepared powders have highly roughened surface. The average particle size of CaSO$_4$ powders ranges from 1 to 5 $\mu$m, indicating homogeneous distribution of particle size. Two reaction steps in the presence of sulfuric acid can be formulated as follows:

$$\text{Ca(OH)}_2 + \text{H}_2\text{SO}_4 = \text{CaSO}_4 + 2\text{H}_2\text{O} \quad (1)$$
$$\text{Ca}^{2+} + \text{SO}_4^{2-} + 2\text{H}_2\text{O} = \text{CaSO}_4\cdot2\text{H}_2\text{O} \quad (2)$$

Basically, the chemical route is capable of producing calcium sulfate (Eq. (1)) or di-hydrated calcium sulfate (Eq. (2)) powders, which are stable at ambient temperature in air (its melting temperature: 1460°C) and can be stored as solid waste without toxicity. Thus, the chemical-wet method shows a scalable feasibility for producing green architecture materials due to its simplicity, high efficiency, and easy operation. To examine its practical applicability for thermal insulation, the porous characteristics of as-prepared CaSO$_4$ powder is further analyzed by physical adsorption of nitrogen. The BET surface area and total pore volume of CaSO$_4$ powders are 102 m$^2$/g and 0.23 cm$^3$/g, respectively. The finding reflects that the CaSO$_4$ powders are porous, allowing a large amount of air trapped in the porous structure.

Thermal imaging photographs for pristine (i.e., CC-1) and CaSO$_4$-containing painting (i.e., CC-3) on the substrates, placed on the hot plate with a stable temperature of approximately 100°C, are illustrated in Fig. 2. It can be observed that the surface temperature of CC-1 sample displays a rapid increase as an increase in time. After 10 min, the temperature of CC-1 sample reaches to approximately 100°C, which is very close to the hot plate. In contrast, the CC-3 sample offers an improved thermal insulation capability, as compared to the CC-1 one. After 10 min, the surface temperature of CC-3 sample only reaches to ~80°C, revealing a strong resistance of thermal conduction in the CC-3 coating.

![Fig. 3](image3.png)

Fig. 3. The surface temperature of the CaSO$_4$-containing painting as a function of heating period.

To inspect the thermal property, the effect of CaSO$_4$ content on the surface temperature of painting is investigated. Fig. 3 evidently indicates that the surface temperature is an
increasing function of heating time for all construction coatings. After 20 min, all construction coatings maintain a stable temperature difference between the hot plate and the CaSO₄-containing coating. As shown in Fig. 4, the CC-3 coating exhibits the lowest ramping rate (i.e., 5.6 °C/min within the first ten minutes) and the highest stable temperature difference (i.e., ~6°C), as compared to the others. As a result, the introduction of CaSO₄ powder is able to provide a thermal barrier, hindering the heat transfer from heat source (i.e., a hot plate used in this case). It is recognized that thermal conductivity of air is approximately 0.026 W/m K [7]. The thermal conductivity of standard gypsum matrix is ~0.60 W/m K [8], 23 times higher than that of air. To support the above argument, Table I shows the porous characteristics of different construction paintings, determined from the data of N₂ adsorption isotherms. It is found that pristine CC-1 sample displays a BET surface area of 10.1 m² g⁻¹, much lower than CC-2 and CC-3 samples. Similarly, the total pore volume of the paintings also delivers the same trend. Accordingly, both the BET surface area and total pore volume are increasing functions of the amount of CaSO₄ powders. Thus, the addition of CaSO₄ powders into the painting is capable of raising the porosity, providing the thermal resistive layer.

\[
\text{CaSO}_4 \cdot 2\text{H}_2\text{O} \ (\text{di}) = \text{CaSO}_4 \cdot 1/2\text{H}_2\text{O} + 3/2 \text{H}_2\text{O} \quad (3)
\]

\[
\text{CaSO}_4 \cdot 1/2\text{H}_2\text{O} (\beta) = \text{CaSO}_4 + 1/2 \text{H}_2\text{O} \quad (4)
\]

The first step can be assigned to the departure of 3/2 mol \text{H}_2\text{O} from dehydrated calcium sulfate, whereas the second one is related to the departure of 1/2 mol \text{H}_2\text{O} from semi-dehydrated calcium sulfate obtained after the incomplete dehydration of dehydrated calcium sulfate and from the \(\beta\)-hemihydrate of plaster (i.e., a phase transformation) [10], [11]. Since both the reaction steps are endothermic, the heat transfer through the gypsum-containing composite painting would be alleviated until the endothermic steps are totally completed [12]. Therefore, the gypsum-containing coating offers a trailing effect, inducing excellent thermal resistance. On the basis of experimental results, the enhanced thermal-insulating performance originates from the fact that the addition of CaSO₄ powders creates a porous framework in the construction coating, inducing an air pocket against heat transfer.

On the basis of experimental results, the addition of CaSO₄ powders significantly increases the amount of air layer against the thermal conduction due to its vast pore structure. Accordingly, the stacking of CaSO₄ powders contains a large amount of air that gives high-quality thermal insulation. The magnitude of thermal conductivity on the composite coating strongly decreases with an increase of fraction of porosity [13]. Accordingly, the larger amount of CaSO₄ powders in the construction coating, the better thermal-insulating performance can attain, due to an air layer trapped in the porous CaSO₄ powders.

To further investigate the practical applicability, one set of experiment regarding the cycleability was performed to identify the thermal insulation performance. Each sample (i.e., CC-1, CC-2, and CC-3 coating) was initially heated to 100°C and then maintained at this temperature for 30 min. The heating rate within 10 min and stable temperature difference were accurately recorded and collected. The variation of heating rate and stable temperature difference with the cycle number is illustrated in Figure 5. It can be seen that all construction coatings display very stable thermal-insulating ability. As expected, the CC-3 coating shows the best thermal-insulation performance among the construction samples. After 10 cycles, the lowest heating rate and the largest temperature difference of CC-3 coating can reach to 5.6 °C/min and 6.2°C, respectively. Thus, the composite coating serves as excellent thermal barrier in a variety of construction applications, especially for green building materials.

Since the as-prepared CaSO₄ powders are free of charge, the prime cost of CaSO₄ powders mainly depends on the amount of dilute sulfuric acid. The cost of hydrated CaSO₄ powders by the as-proposed method is thus estimated to be

![Fig. 4. The heating rate and stable temperature difference as a function of CaSO₄ content.](image)

![Fig. 5. The heating rate and stable temperature difference as a function of cycle number.](image)
approximately 0.18 US dollar/kg, based on the 100 % conversion (i.e., the chemical reaction (R1): Ca(OH)$_2$ + H$_2$SO$_4$ ≡ CaSO$_4$ + 2H$_2$O) and the usage of industrial-grade reagents. The unit price of home-made CaSO$_4$ powders is much less than that of commercial products (i.e., 2–10 US dollar/kg). Thus, the simple chemical-wet synthesis of CaSO$_4$ powders from waste solid offers a promising feasibility for commercialization due to its low cost and eco-friendless.

IV. CONCLUSION

We have presented an improved thermal resistance from the construction coating mixed with CaSO$_4$ powders, prepared from the chemical-wet approach using toxic Ca(OH)$_2$ waste as precursor. The efficient chemical-wet approach was prone to produce CaSO$_4$ and CaSO$_4$·2H$_2$O powders, which could be stable in air and easily stored as solid waste. The low heating rate and high stable temperature difference revealed that the addition of CaSO$_4$ powders offers a strong thermal barrier against the thermal transfer from heat source. Since the CaSO$_4$ powders were prepared from industrial solid waste, the simple chemical-wet method delivered a potential pathway to produce green construction materials for various applications owing to its simplicity, high recycling ratio, non-toxicity, low cost, and environmental friendliness.
